`opalalgorithms` provides an interface to implement algorithms to be used in OPAL project. Each algorithm will be run using multiprocessing library.

Creating algorithm has two main parts to it

- implementation
- testing

`opalalgorithms` provides you with utilities to do both.

## 1.1 implementation

We use `opalalgorithms.core.base` that provides utilities for implementing an algorithm for OPAL. An algorithm will look like as follows:

```
"""Sample algorithm 1 to return home of users."""
from __future__ import division, print_function
from opalalgorithms.core import OPALAlgorithm

class SampleAlgol(OPALAlgorithm):
    """Calculate population density."""

    def __init__(self):
        """Initialize population density."""
        super(SampleAlgol, self).__init__()

    def map(self, params, bandicoot_user):
        """Get home of the bandicoot user.

        Args:
            params (dict): Request parameters.
            bandicoot_user (bandicoot.core.User): Bandicoot user object.

        """
```

(continues on next page)

(continued from previous page)

```
home = bandicoot_user.recompute_home()
if not home:
    return None
return {getattr(home, params["resolution"]): 1}
```

## 1.2 testing

We provide utilities to test the algorithm you create. Before running the algorithm, it is advised you setup the apparmor and codejail as mentioned [here](#).

Use `tests/generate_data.py` to generate data after installing the opalgorithms library. You can run your algorithm with the following code:

```
"""Test population density algorithm."""
from __future__ import division, print_function
from opalgorithms.utils import AlgorithmRunner

num_threads = 3
data_path = 'data'

def get_algo(filename):
    algorithm = dict(
        code=open(filename).read(),
        className='ClassNameOfYourAlgo'
    )
    return algorithm

def run_algo(algorithm_filename, params):
    """Run an algorithm."""
    algorithm = get_algo(algorithm_filename)
    alorunner = AlgorithmRunner(
        algorithm, dev_mode=False, multiprocess=True, sandboxing=True)
    result = alorunner(params, data_path, num_threads)
    return result

if __name__ == '__main__':
    """Test that algorithm runner runs successfully."""
    params = dict(
        sample=0.2,
        resolution='location_level_1')
    assert run_algo('/path/to/your/algo.py', params)
```

This library provides an interface and tools for implementation of algorithms to be used in OPAL project.

## 2.1 opalalgorithms.core

This is the core library of opalalgorithms which specifies the standard class which is to be inherited when implementing any algorithm for opal project.

### 2.1.1 opalalgorithms.core.base

This is the base module for all algorithms.

Base class for implementing any algorithms for OPAL computation.

**class** opalalgorithms.core.base.OPALAlgorithm

Base class for OPAL Algorithms.

The class can be used in the following way:

```
algo = OPALAlgorithm()
result = algo.map(params, bandicoot_user)
```

**map** (*params*, *bandicoot\_user*)

Map users data to a single result.

#### Parameters

- **params** (*dict*) – Parameters to be used by each map of the algorithm.
- **bandicoot\_user** (*bandicoot.user*) – [Bandicoot user](#).

**Returns** A dictionary representing with keys as string or tuple, and values as int or float which will be aggregated by the reducer.

**Return type** *dict*

## 2.1.2 opalalgorithms.core.base

This is the base module for all privacy algorithms to be applied on result.

Base class for implementing any privacy algorithms for OPAL computation.

**class** opalalgorithms.core.privacy.OPALPrivacy

Base class for OPAL Privacy Algorithms.

The class can be used in the following way:

```
privacyalgo = OPALPrivacy()
result = privacyalgo(params, result, salt)
```

## 2.2 opalalgorithms.utils

Utilities for testing opalalgorithms and running them.

### 2.2.1 opalalgorithms.utils.datagenerator

Data generator class for generating data for testing purposes.

**class** opalalgorithms.utils.datagenerator.OPALDataGenerator (*num\_antennas,*  
*num\_antennas\_per\_user,*  
*num\_records\_per\_user,*  
*bandi-*  
*coot\_extended=True*)

Generate data as per OPAL formats for testing purposes.

#### Parameters

- **num\_antennas** (*int*) – Total number of antennas available.
- **num\_antennas\_per\_user** (*int*) – Total number of different antennas a user can connect to.
- **num\_records\_per\_user** (*int*) – Number of records generated for each user over the complete year.
- **bandicoot\_extended** (*bool*) – To use bandicoot extended format or old format.

---

#### Todo:

- Remove bandicoot extended once that library is fixed.
- 

**generate\_data** ()

Generate data for a single user.

### 2.2.2 opalalgorithms.utils.algorithmrunner

Algorithm runner class to run algorithms during computation.

Given an algorithm object, run the algorithm.

```
opalalgorithms.utils.algorithmrunner.mapper(writing_queue, params, file_queue, algo-
                                             rithm, dev_mode=False, sandboxing=True,
                                             python_version=2)
```

Call the map function and insert result into the queue if valid.

#### Parameters

- **writing\_queue** (*mp.manager.Queue*) – Queue for inserting results.
- **params** (*dict*) – Parameters to be used by each map of the algorithm.
- **users\_csv\_files** (*list*) – List of paths of csv files of users.
- **algorithm** (*dict*) – Dictionary with keys *code* and *className* specifying algorithm code and className.
- **dev\_mode** (*bool*) – Should the algorithm run in development mode or production mode.
- **sandboxing** (*bool*) – Should sandboxing be used or not.
- **python\_version** (*int*) – Python version being used for sandboxing.

```
opalalgorithms.utils.algorithmrunner.collector(writing_queue, params,
                                                dev_mode=False)
```

Collect the results in writing queue and post to aggregator.

#### Parameters

- **writing\_queue** (*mp.manager.Queue*) – Queue from which collect results.
- **results\_csv\_path** (*str*) – CSV where we have to save results.
- **dev\_mode** (*bool*) – Whether to run algorithm in development mode.

**Returns** True on successful exit if *dev\_mode* is set to False.

**Return type** `bool`

---

**Note:** If *dev\_mode* is set to true, then collector will just return all the results in a list format.

---

```
opalalgorithms.utils.algorithmrunner.is_valid_result(result)
```

Check if result is valid.

**Parameters** **result** – Output of the algorithm.

---

**Note:** Result is valid if it is a dict. All keys of the dict must be a string. All values must be numbers. These results are sent to reducer which will sum, count, mean, median, mode of the values belonging to same key.

#### Example:

- {"alpha1": 1, "ant199": 1, ..}
- 

**Returns** Specifying if the result is valid or not.

**Return type** `bool`

---

#### Todo:

- Define what is valid with privacy and other concerns
-

`opalalgorithms.utils.algorithmrunner.process_user_csv` (*params*, *user\_csv\_file*, *algorithm*, *dev\_mode*, *sandboxing*, *jail*)

Process a single user csv file.

#### Parameters

- **params** (*dict*) – Parameters for the request.
- **user\_csv\_file** (*string*) – Path to user csv file.
- **algorithm** (*dict*) – Dictionary with keys *code* and *className* specifying algorithm code and className.
- **dev\_mode** (*bool*) – Should the algorithm run in development mode or production mode.
- **sandboxing** (*bool*) – Should sandboxing be used or not.
- **jail** (*codejail.Jail*) – Jail object.

**Returns** Result of the execution.

**Raises** `SafeExecException` – If the execution wasn't successful.

`opalalgorithms.utils.algorithmrunner.get_jail` (*python\_version=2*)  
Return codejail object.

---

#### Note:

- Please set environmental variables `OPALALGO_SANDBOX_VENV` and `OPALALGO_SANDBOX_USER` before calling this function.
  - `OPALALGO_SANDBOX_VENV` must be set to the path of the sandbox virtual environment.
  - `OPALALGO_SANDBOX_USER` must be set to the user running the sandboxed algorithms.
- 

**class** `opalalgorithms.utils.algorithmrunner.AlgorithmRunner` (*algorithm*,  
*dev\_mode=False*,  
*multiprocess=True*,  
*sandboxing=True*)

Algorithm runner.

#### Parameters

- **algorithm** (*dict*) – Dictionary containing *code* and *className*.
- **dev\_mode** (*bool*) – Development mode switch
- **multiprocess** (*bool*) – Use multiprocessing or single process for complete execution.
- **sandboxing** (*bool*) – Use sandboxing for execution or execute in unsafe environment.

**\_\_call\_\_** (*params*, *data\_dir*, *num\_threads*, *weights\_file=None*)  
Run algorithm.

Selects the csv files from the data directory. Divides the csv files into chunks of equal size across the *num\_threads* threads. Each thread performs calls map function of the csv file and processes the result. The collector thread, waits for results before posting it to aggregator service.

#### Parameters

- **params** (*dict*) – Dictionary containing all the parameters for the algorithm
- **data\_dir** (*str*) – Data directory with csv files.

- **num\_threads** (*int*) – Number of threads
- **weights\_file** (*str*) – Path to the json file containing weights.

**Returns** Amount of time required for computation in microseconds.

**Return type** `int`

### 2.2.3 opalalgorithms.utils.date\_helper

Utility functions to help manipulate dates within different algorithms.

`opalalgorithms.utils.date_helper.is_date_between(start, end, date)`

Check if data is between start and end datetime.

**Parameters**

- **start** (*string*) – Starting datetime, must be of form ‘%Y-%m-%d %H:%M:%S’
- **end** (*string*) – Ending datetime, must be of form ‘%Y-%m-%d %H:%M:%S’
- **date** (*string*) – Date to be checked, must be of form ‘%Y-%m-%d %H:%M:%S’

**Returns** Whether date is between end and start date.

**Return type** `bool`

`opalalgorithms.utils.date_helper.is_date_greater(ref, date)`

Check if date is greater than reference time.

**Parameters**

- **ref** (*string*) – Reference datetime against which we need to check, must be of form ‘%Y-%m-%d %H:%M:%S’.
- **date** (*string*) – Date which is to be checked, must be of form ‘%Y-%m-%d %H:%M:%S’

**Returns** Whether date is greater than reference.

**Return type** `bool`

## CHAPTER 3

---

### Indices and tables

---

- `genindex`
- `modindex`
- `search`

### O

- `opalalgorithms.core.base`, 5
- `opalalgorithms.core.privacy`, 6
- `opalalgorithms.utils.algorithmrunner`, 6
- `opalalgorithms.utils.datagenerator`, 6
- `opalalgorithms.utils.date_helper`, 9

## Symbols

`__call__()` (*opalalgorithms.utils.algorithmrunner.AlgorithmRunner* method), 8

## A

`AlgorithmRunner` (class in *opalalgorithms.utils.algorithmrunner*), 8

## C

`collector()` (in module *opalalgorithms.utils.algorithmrunner*), 7

## G

`generate_data()` (*opalalgorithms.utils.datagenerator.OPALDataGenerator* method), 6

`get_jail()` (in module *opalalgorithms.utils.algorithmrunner*), 8

## I

`is_date_between()` (in module *opalalgorithms.utils.date\_helper*), 9

`is_date_greater()` (in module *opalalgorithms.utils.date\_helper*), 9

`is_valid_result()` (in module *opalalgorithms.utils.algorithmrunner*), 7

## M

`map()` (*opalalgorithms.core.base.OPALAlgorithm* method), 5

`mapper()` (in module *opalalgorithms.utils.algorithmrunner*), 6

## O

`OPALAlgorithm` (class in *opalalgorithms.core.base*), 5

*opalalgorithms.core.base* (module), 5

*opalalgorithms.core.privacy* (module), 6

*opalalgorithms.utils.algorithmrunner* (module), 6

*opalalgorithms.utils.datagenerator* (module), 6

*opalalgorithms.utils.date\_helper* (module), 9

*OPALDataGenerator* (class in *opalalgorithms.utils.datagenerator*), 6

*OPALPrivacy* (class in *opalalgorithms.core.privacy*), 6

## P

`process_user_csv()` (in module *opalalgorithms.utils.algorithmrunner*), 7
